331 Final

Spring 2011

Details

- 6-8 pm next Monday
- Comprehensive with more emphasis on material since the midterm
- Study example finals and midterm exams from earlier semesters
- Read assigned material from book and schedule

For each of the following grammars, briefly describe the language it defines in a sentence or two. Assume that the start symbol is S for each and that any symbol found only on the right hand side of a production is a terminal symbol.

(1b) 5 points.

 $S \rightarrow B A$

S -> a

 $B \rightarrow S A$

 $A \rightarrow a$

For each of the following grammars, briefly describe the language it defines in a sentence or two. Assume that the start symbol is S for each and that any symbol found only on the right hand side of a production is a terminal symbol.

(1c) 5 points.

$$S \rightarrow a X$$

$$S \rightarrow b S b$$

(a) Draw a DFA for a real number that satisfies the following description, using the conventions above.

A real number can start with an optional sign which can be "-" or "+" and consists of an integer part followed by a decimal point followed by a fractional part. The integer part can be a single zero or a non-empty sequence of digits that does not start with a zero. The fractional part is a non-empty sequence of digits. Positive examples include 0.0, +0.0, 0.12, 12.3 and -9.87. Negative examples are: 0, 01.2, -01.2, 3. and 42.

Identify the start state and all accepting states and label every arc. Since this is a deterministic and not a non-deterministic finite automaton, every arc must have a label which can not be epsilon.

(b) Write a regular expression that corresponds to the DFA, making it as simple as possible. Use parentheses to ensure proper scope or for clarity. (15 points)

Assuming that we've done (define x '((1 (2)) (3))) give a Scheme expression using only the functions car and cdr and variable x that returns the second symbol in the list

Common Lisp has a built-in function maplist. The Scheme counterpart could be written as follows:

Consider a function insert with three arguments: an arbitrary s-expression, a proper list, and a positive integer. The function returns a new list that is the result of inserting the expression into the list at the position specified by the third argument. Note that positions begin with zero. For example,

```
>> (insert 'X '(a b c) 3)
(a b c X d)
>> (insert '(X) '(a b c) 1)
(a (X) b c)
>> insert 'X '(a b c) 0)
(X a b c)
```

Here is an incomplete definition of the function. Give code expressions for <S1>, <S2> and <S3> that will complete it.

Perl (or Lisp)

Write a function weight that takes a single argument and returns its weight, where the weight of a non-list is 1 and the weight of a list of N elements is N plus the sum of the weights of the elements.
