

# Mobility

## *Legs, Wheels, and Wings*

# Today's Class

2

- ◆ Useful terminology
  - ◆ Degrees of Freedom
  - ◆ Compliance and back-drive
  - ◆ Actuator saturation
  - ◆ Slip
- ◆ Mechanics: 3 most common mobility actuators
  - ◆ Legs, wheels, wings/propellers
- ◆ Other mobile actuators
- ◆ Walking wheels, passive flight, swimming, ...

# Characterizing Locomotion

3

- ◆ Locomotion:
  - ◆ Physical interaction between robot and environment.
  - ◆ Locomotion is concerned with:
    - ◆ Interaction forces; mechanisms and actuators that generate them
- ◆ The most important issues in locomotion are:
  - ◆ Stability
    - ◆ Center of gravity
    - ◆ Static/dynamic stabilization
    - ◆ Inclination of terrain
  - ◆ Contact
    - ◆ Contact point(s)
    - ◆ Contact area
    - ◆ Angle of Contact
    - ◆ Friction
- ◆ Type of environment
  - ◆ Water, air, soft or hard ground

# Degrees of Freedom

4

- ◆ DoFs
  - ◆ Number of independent parameters that define the **state** (not location!) of a physical system.

# Compliance / Back-drive

5

- ◆ Motion of a DoF in response to external force
  - ◆ High compliance: moves a lot when stressed
  - ◆ Low compliance: stiff system when stressed
- ◆ Active compliance: software recognizes motion
- ◆ Passive compliance: mechanical structure
- ◆ Back-driveable means that you can physically move it (without breaking it) – passive compliance
  - ◆ Mostly a product of motor and gear type

# Slip and Saturation

6

- ◆ Actuator saturation: physical performance limit
- ◆ Generally, saturation is a nonlinear response.
- ◆ Example: electric motor
  - ◆ Driving circuit has amp limit
  - ◆ Result: torque or speed limit.
  - ◆ When limit is exceeded, components start to burn out
  - ◆ Hard, nonlinear limit
- ◆ Slip: some interface (friction, gears, ...) fail to catch
  - ◆ Examples: tires on snow; overdriven motor

# Legged Locomotion

7

- ◆ Locomotion Concepts
- ◆ Nature came up with many approaches
  - ◆ Difficult to imitate technically
  - ◆ Do not employ wheels
  - ◆ Sometimes imitate wheels (bipedal walking)
- ◆ Adaptation to environment
- ◆ Most technical systems today use wheels
  - ◆ Legged locomotion is still mostly research

# Legged Motion

8

- ◆ Fewer legs → more complicated mechanically
  - ◆ Static stability
    - ◆ With **point** contact - at least three legs are required for static stability
    - ◆ With **surface** contact – at least one leg is required
  - ◆ During walking some (usually half) of legs are lifted
    - ◆ Losing stability?
  - ◆ For **static walking** 4+ legs are required
    - ◆ Animals usually move two legs at a time
    - ◆ Humans require more than a year

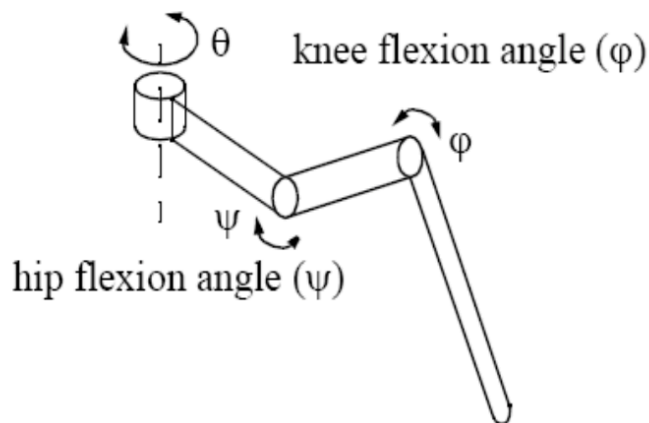

# Leg Joints (DoFs)

9

- ◆ 2+ DoFs to move a leg forward: **lift** and **swing**
- ◆ Three DoFs for each leg in most cases
  - ◆ 4th DOF for the ankle joint
  - ◆ Might improve walking and stability
  - ◆ Additional joints increase design and control complexity

# Gait Options

10

- ◆ The number of distinct event sequences (gaits)
  - ◆ Distinct sequence of lift and release events of individual legs
  - ◆ Depends on number of legs
- ◆ Number of possible events  $N$  with  $k$  legs is:

$$N = (2k - 1)!$$

- ◆ For a biped ( $k=2$ ), number of possible events  $N$  is:

$$N = (2k-1)! = 3! = 3 \cdot 2 \cdot 1 = 6$$

- ◆ For a robot with 6 legs (hexapod)  $N$  is:

$$N = 11! = 39,916,800$$

# Gait Options

11

- ◆ Two legs (biped) can have four different states:
  - ◆ Both legs down
  - ◆ Right leg down, left leg up
  - ◆ Right leg up, left leg down
  - ◆ Both legs up

● *Leg down*  
○ *Leg up*

- ◆ **Event sequence:** go from one state to another and back

1 -> 2 -> 1   ● ○ ● → *turning on right leg*

2 -> 3 -> 2   ○ ● ○ → *walking running*

1 -> 3 -> 1   ● ● ● → *turning on left leg*

2 -> 4 -> 2   ○ ○ ○ → *hopping right leg*

1 -> 4 -> 1   ● ○ ● → *hopping with two legs*

3 -> 4 -> 3   ● ○ ● → *hopping left leg*

# Static vs. Dynamic Walking

12

## ◆ Statically stable

- ◆ Bodyweight supported by at least three legs
- ◆ Even if all joints freeze, the robot will not fall
- ◆ Safe  $\leftrightarrow$  slow and inefficient

## ◆ Dynamic walking

- ◆ Robot will fall if not continuously moving
- ◆ Fewer than three legs can be in ground contact
- ◆ Fast, efficient  $\leftrightarrow$  harder actuation and control

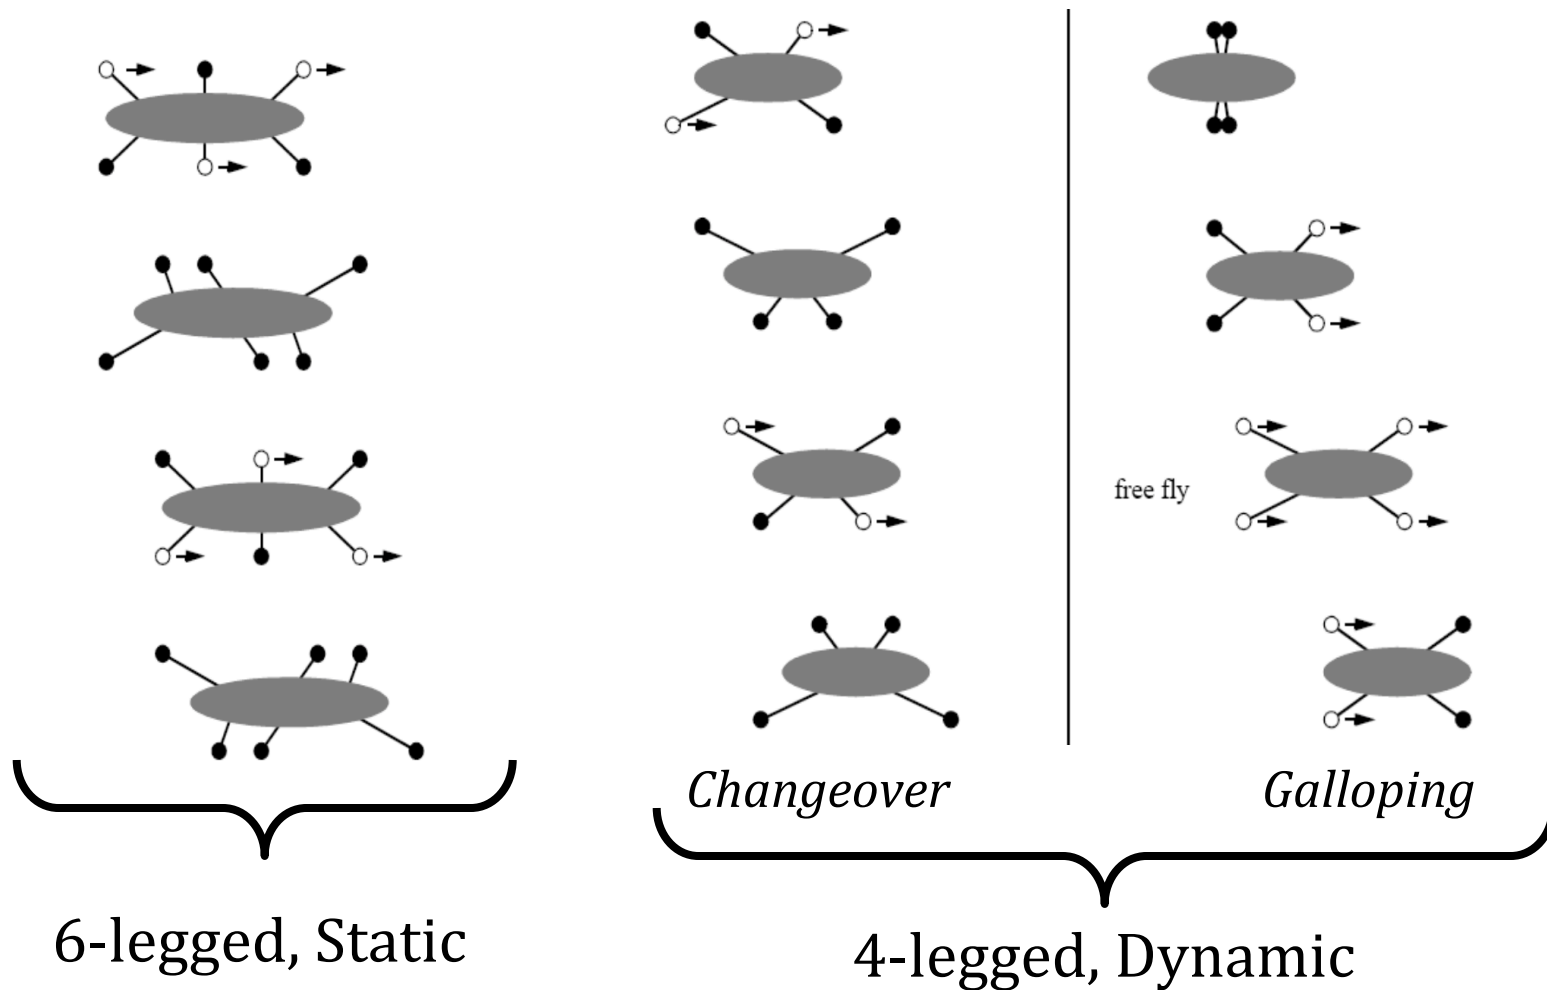

# Static vs. Dynamic Gait

13

- ◆ Whether robot is stable at all times during walking (static)

# Passive Dynamic Walking

14

- ◆ Gravity-powered walking with bipedal gait

# Wheels

17

- ◆ Most appropriate solution for most applications
- ◆ Three wheels guarantee stability
- ◆ With more than three wheels an appropriate **suspension** is required
  - ◆ Why?
- ◆ Selection of wheels depends on the application

# Basic Wheel Types

18

- ◆ Standard wheel
  - ◆ Two degrees of freedom
  - ◆ Rotation around the (motorized) wheel axle and the contact point
  
- ◆ Castor wheel
  - ◆ Three degrees of freedom
  - ◆ Rotation around the wheel axle, the contact point and the castor axle

We will pick up here next time.

# Basic Wheel Types

19

- ◆ Swedish (Mecanum, Ilon) wheel
  - ◆ Three degrees of freedom
  - ◆ Rotation around the
  - ◆ (motorized) wheel axle, rollers, contact point

# Basic Wheel Types

20

[https://www.youtube.com/watch?v=8sH1a511\\_q4](https://www.youtube.com/watch?v=8sH1a511_q4)

# Basic Wheel Types

21

- ◆ Ball or spherical wheel
  - ◆ Suspension not solved

# Characterization: Stability

22

- ◆ Stability of a vehicle is guaranteed with 3 wheels
  - ◆ If center of gravity is within the triangle which formed by the ground contact point of the wheels

- ◆ Stability is improved by 4+ wheels
  - ◆ However, arrangements require a flexible suspension
  - ◆ Why?

# Characterization

23

- ◆ Bigger wheels overcome higher obstacles
  - ◆ But require higher torque or reductions in the gear box
- ◆ Most wheel arrangements require high control effort
  - ◆ Non-holonomic – we'll get into that in Ch. 3
- ◆ Combining actuation and steering on a single wheel
  - ◆ Makes the design complex
  - ◆ Adds errors for **odometry**
    - ◆ Data from motion sensors used to estimate position
    - ◆ "Dead reckoning"

# Synchro Drive

24

- ◆ All wheels are actuated synchronously by one motor
  - ◆ Defines the speed of the vehicle
- ◆ All wheels steered synchronously by a second motor
  - ◆ Sets the heading of the vehicle
- ◆ Orientation in space of robot frame will always remain the same
- ◆ Not possible to control orientation of robot frame
