*Asymptotic Analysis*

# Complexity

How many resources will it take to solve a problem of a given size?

- time
- space

Expressed as a function of problem size (beyond some minimum size)

- how do requirements grow as size grows?

Problem size

- number of elements to be handled
- size of thing to be operated on

# Mileage Example

Problem:

John drives his car, how much gas does he use?

# The Goal of Asymptotic Analysis

How to analyze the running time (aka computational complexity) of an algorithm in a theoretical model.

Using a theoretical model allows us to ignore the effects of

- Which computer are we using?
- How good is our compiler at optimization

We define the running time of an algorithm with input size  $n$  as  $T(n)$  and examine the rate of growth of  $T(n)$  as  $n$  grows larger and larger.

# Growth Functions

Constant

$$T(n) = c$$

ex: getting array element at known location  
trying on a shirt  
calling a friend for fashion advice

Linear

$$T(n) = cn \text{ [+ possible lower order terms]}$$

ex: finding particular element in array (sequential search)  
trying on all your shirts  
calling all your n friends for fashion advice

## Growth Functions (cont)

### Quadratic

$T(n) = cn^2$  [ + possible lower order terms]

- ex: sorting all the elements in an array (using bubble sort)
- trying all your shirts ( $n$ ) with all your ties ( $n$ )
- having conference calls with each pair of  $n$  friends

### Polynomial

$T(n) = cn^k$  [ + possible lower order terms]

- ex: looking for maximum substrings in array
- trying on all combinations of  $k$  separates types of apparels ( $n$  of each)
- having conferences calls with each  $k$ -tuple of  $n$  friends

# Growth Functions (cont)

## Exponential

$T(n) = c^n$  [+ possible lower order terms]

ex: constructing all possible orders of array elements

## Logarithmic

$T(n) = \lg n$  [+ possible lower order terms]

ex: finding a particular array element (binary search)  
trying on all Garanimal combinations  
getting fashion advice from n friends using phone tree

# A graph of Growth Functions

# Expanded Scale

# Asymptotic Analysis

What happens as problem size grows really, really large? (in the limit)

- constants don't matter
- lower order terms don't matter

# Analysis Cases

What particular input (of given size) gives worst/best/average complexity?

**Best Case:** If there is a permutation of the input data that minimizes the “run time efficiency”, then that minimum is the best case run time efficiency

**Worst Case:** If there is a permutation of the input data that maximizes the “run time efficiency”, then that maximum is the best case run time efficiency

Mileage example: how much gas does it take to go 20 miles?

- Worst case: all uphill
- Best case: all downhill, just coast
- Average case: “average terrain”

## Cases Example

Consider sequential search on an unsorted array of length  $n$ ,  
what is time complexity?

Best case:

Worst case:

Average case:

## Definition of Big-Oh

$T(n) = O(f(n))$  (read “ $T(n)$  is in Big-Oh of  $f(n)$ ”) if and only if

$T(n) \leq cf(n)$  for some constants  $c$ ,  $n_0$  and  $n \geq n_0$

This means that eventually (when  $n \geq n_0$ ),  $T(n)$  is always less than or equal to  $c$  times  $f(n)$ .

The growth rate of  $T(n)$  is less than or equal to that of  $f(n)$

Loosely speaking,  $f(n)$  is an “upper bound” for  $T(n)$

## Big-Oh Example

Suppose we have an algorithm that reads  $N$  integers from a file and does something with each integer.

The algorithm takes some constant amount of time for initialization (say 500 time units) and some constant amount of time to process each data element (say 10 time units).

For this algorithm, we can say  $T(N) = 500 + 10N$ .

The following graph shows  $T(N)$  plotted against  $N$ , the problem size and  $20N$ .

Note that the function  $N$  will *never* be larger than the function  $T(N)$ , no matter how large  $N$  gets. But there are constants  $c_0$  and  $n_0$  such that  $T(N) \leq c_0N$  when  $N \geq n_0$ , namely  $c_0 = 20$  and  $n_0 = 50$ .

Therefore, we can say that  $T(N)$  is in  $O(N)$ .

# T(N) vs. N vs. 20N

## Simplifying Assumptions

1. If  $f(n) = O(g(n))$  and  $g(n) = O(h(n))$ , then  $f(n) = O(h(n))$
2. If  $f(n) = O(kg(n))$  for any  $k > 0$ , then  $f(n) = O(g(n))$
3. If  $f_1(n) = O(g_1(n))$  and  $f_2(n) = O(g_2(n))$ ,  
then  $f_1(n) + f_2(n) = O(\max(g_1(n), g_2(n)))$
4. If  $f_1(n) = O(g_1(n))$  and  $f_2(n) = O(g_2(n))$ ,  
then  $f_1(n) * f_2(n) = O(g_1(n) * g_2(n))$

# Example

Code:

```
a = b;
```

Complexity:

# Example

Code:

```
sum = 0;
for (i = 1; i <= n; i++)
    sum += n;
```

Complexity:

## Example

Code:

```
sum1 = 0;
for (i = 1; i <= n; i++)
    for (j = 1; j <= n; j++)
        sum1++;
```

Complexity:

## Example

Code:

```
sum2 = 0;
for (i = 1 ; i <= n; i++)
    for (j = 1; j <= i; j++)
        sum2++;
```

Complexity:

# Example

Code:

```
sum = 0;
for (j = 1; j <= n; j++)
    for (i = 1; i <= j; i++)
        sum++;
for (k = 0; k < n; k++)
    A[ k ] = k;
```

Complexity:

## Example

Code:

```
sum1 = 0;
for (k = 1; k <= n; k *= 2)
    for (j = 1; j <= n; j++)
        sum1++;
```

Complexity:

## Example

Code:

```
sum2 = 0;
for (k = 1; k <= n; k *= 2)
    for (j = 1; j <= k; j++)
        sum2++;
```

Complexity:

## Example

- Square each element of an  $N \times N$  matrix
- Printing the first and last row of an  $N \times N$  matrix
- Finding the smallest element in a sorted array of  $N$  integers
- Printing all permutations of  $N$  distinct elements

# Space Complexity

Does it matter?

What determines space complexity?

How can you reduce it?

What tradeoffs are involved?

# Constants in Bounds

Theorem:

If  $T(x) = O(cf(x))$ , then  $T(x) = O(f(x))$

Proof:

- $T(x) = O(cf(x))$  implies that there are constants  $c_0$  and  $n_0$  such that  $T(x) \leq c_0(cf(x))$  when  $x \geq n_0$
- Therefore,  $T(x) \leq c_1(f(x))$  when  $x \geq n_0$  where  $c_1 = c_0c$
- Therefore,  $T(x) = O(f(x))$

## Sum in Bounds

**Theorem:**

Let  $T_1(n) = O(f(n))$  and  $T_2(n) = O(g(n))$ .

Then  $T_1(n) + T_2(n) = O(\max(f(n), g(n)))$ .

**Proof:**

- From the definition of  $O$ ,  $T_1(n) \leq c_1 f(n)$  for  $n \geq n_1$  and  $T_2(n) \leq c_2 g(n)$  for  $n \geq n_2$
- Let  $n_0 = \max(n_1, n_2)$ .
- Then, for  $n \geq n_0$ ,  $T_1(n) + T_2(n) \leq c_1 f(n) + c_2 g(n)$
- Let  $c_3 = \max(c_1, c_2)$ .
- Then,  $T_1(n) + T_2(n) \leq c_3 f(n) + c_3 g(n)$   
 $\leq 2c_3 \max(f(n), g(n))$   
 $\leq c \max(f(n), g(n))$   
 $= O(\max(f(n), g(n)))$

# Products in Bounds

Theorem:

Let  $T_1(n) = O(f(n))$  and  $T_2(n) = O(g(n))$ .

Then  $T_1(n) * T_2(n) = O(f(n) * g(n))$ .

Proof:

- Since  $T_1(n) = O(f(n))$ , then  $T_1(n) \leq c_1 f(n)$  when  $n \geq n_1$
- Since  $T_2(n) = O(g(n))$ , then  $T_2(n) \leq c_2 g(n)$  when  $n \geq n_2$
- Hence  $T_1(n) * T_2(n) \leq c_1 * c_2 * f(n) * g(n)$  when  $n \geq n_0$   
where  $n_0 = \max(n_1, n_2)$
- And  $T_1(n) * T_2(n) \leq c * f(n) * g(n)$  when  $n \geq n_0$   
where  $n_0 = \max(n_1, n_2)$  and  $c = c_1 * c_2$
- Therefore, by definition,  $T_1(n) * T_2(n) = O(f(n) * g(n))$ .

# Polynomials in Bounds

**Theorem:**

If  $T(n)$  is a polynomial of degree  $k$ , then  $T(n) = O(n^k)$ .

**Proof:**

- $T(n) = n^k + n^{k-1} + \dots + c$  is a polynomial of degree  $k$ .
- By the sum rule, the largest term dominates.
- Therefore,  $T(n) = O(n^k)$ .

# L'Hospital's Rule

Finding limit of ratio of functions as variable approaches  $\infty$

$$\lim_{x \rightarrow \infty} \frac{f(x)}{g(x)} = \lim_{x \rightarrow \infty} \frac{f'(x)}{g'(x)}$$

Use to determine  $O$  ordering of two functions

$$f(x) = O(g(x)) \text{ if } \lim_{x \rightarrow \infty} \frac{f(x)}{g(x)} = 0$$

# Polynomials of Logarithms in Bounds

Theorem:

$\lg^k n = O(n)$  for any positive constant  $k$

Proof:

- Note that  $\lg^k n$  means  $(\lg n)^k$ .
- Need to show  $\lg^k n \leq cn$  for  $n \geq n_0$ . Equivalently, can show  $\lg n \leq cn^{1/k}$
- Letting  $a = 1/k$ , we will show that  $\lg n = O(n^a)$  for any positive constant  $a$ . Use L'Hospital's rule:

$$\lim_{n \rightarrow \infty} \frac{\lg n}{cn^a} = \lim_{n \rightarrow \infty} \frac{\lg e}{n} = \lim_{n \rightarrow \infty} \frac{c_2}{n^a} = 0$$

Ex:  $\lg^{1000000}(n) = O(n)$

# Polynomials vs Exponentials in Bounds

Theorem:

$$n^k = O(a^n) \text{ for } a > 1$$

Proof:

- Use L'Hospital's rule

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{n^k}{a^n} &= \lim_{n \rightarrow \infty} \frac{kn^{k-1}}{a^n \ln a} \\ &= \lim_{n \rightarrow \infty} \frac{k(k-1)n^{k-2}}{a^n \ln^2 a} \\ &\dots \\ &= \lim_{n \rightarrow \infty} \frac{k(k-1)\dots 1}{a^n \ln^k a} \\ &= 0 \end{aligned}$$

9/6/2006 Ex:  $n^{1000000} = O(1.00000001^n)$

# Relative Orders of Growth

## An Exercise

$n$  (linear)

$\log^k n$  for  $0 < k < 1$

constant

$n^{1+k}$  for  $k > 0$  (polynomial)

$2^n$  (exponential)

$n \log n$

$\log^k n$  for  $k > 1$

$n^k$  for  $0 < k < 1$

$\log n$

# Big-Oh is not the whole story

Suppose you have a choice of two approaches to writing a program. Both approaches have the same asymptotic performance (for example, both are  $O(n \lg(n))$ ). Why select one over the other, they're both the same, right? They may not be the same. There is this small matter of the constant of proportionality.

Suppose algorithms **A** and **B** have the same asymptotic performance,  $T_A(n) = T_B(n) = O(g(n))$ . Now suppose that **A** does 10 operations for each data item, but algorithm **B** only does 3. It is reasonable to expect **B** to be faster than **A** even though both have the same asymptotic performance. The reason is that asymptotic analysis ignores constants of proportionality.

The following slides show a specific example.

# Algorithm A

Let's say that algorithm A is

```
{
  initialization // takes 50 units
  read in n elements into array A; // 3 units per element
  for (i = 0; i < n; i++)
  {
    do operation1 on A[i]; // takes 10 units
    do operation2 on A[i]; // takes 5 units
    do operation3 on A[i]; // takes 15 units
  }
}
```

$$T_A(n) = 50 + 3n + (10 + 5 + 15)n = 50 + 33n$$

## Algorithm B

Let's now say that algorithm B is

```
{
  initialization // takes 200 units
  read in n elements into array A; // 3 units per element
  for (i = 0; i < n; i++)
  {
    do operation1 on A[i]; // takes 10 units
    do operation2 on A[i]; /takes 5 units
  }
}
```

$$T_B(n) = 200 + 3n + (10 + 5)n = 200 + 18n$$

# $T_A(n)$ vs. $T_B(n)$

## A concrete example

The following table shows how long it would take to perform  $T(n)$  steps on a computer that does 1 billion steps/second. Note that a microsecond is a millionth of a second and a millisecond is a thousandth of a second.

N	$T(n) = n$	$T(n) = n \lg n$	$T(n) = n^2$	$T(n) = n^3$	$Tn = 2^n$
5	0.005 microsec	0.01 microsec	0.03 microsec	0.13 microsec	0.03 microsec
10	0.01 microsec	0.03 microsec	0.1 microsec	1 microsec	1 microsec
20	0.02 microsec	0.09 microsec	0.4 microsec	8 microsec	1 millisc
50	0.05 microsec	0.28 microsec	2.5 microsec	125 microsec	13 days
100	0.1 microsec	0.66 microsec	10 microsec	1 millisc	$4 \times 10^{13}$ years

Notice that when  $n \geq 50$ , the computation time for  $T(n) = 2^n$  has started to become too large to be practical. This is most certainly true when  $n \geq 100$ . Even if we were to increase the speed of the machine a million-fold,  $2^n$  for  $n = 100$  would be 40,000,000 years, a bit longer than you might want to wait for an answer.
