

## Chapter 3: Processes

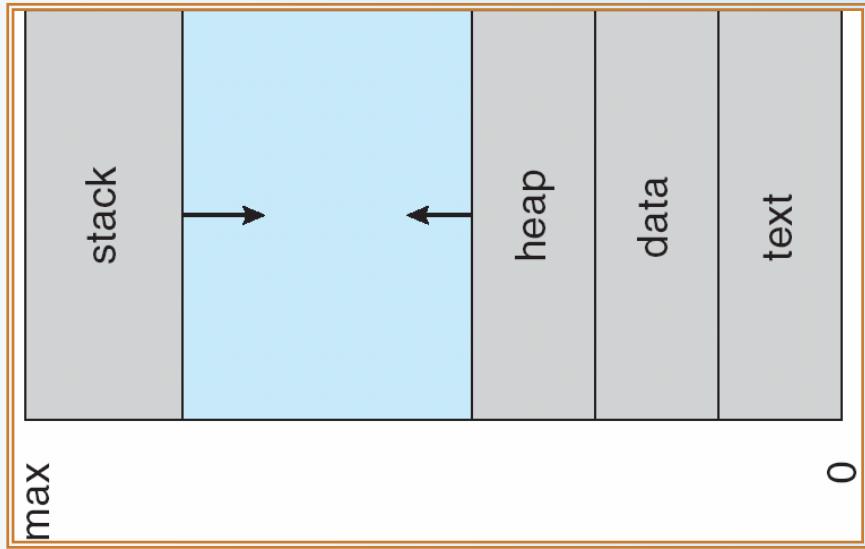

# Process Concept

- An operating system executes a variety of programs:
  - Batch system – jobs
  - Time-shared systems – user programs or tasks
- Textbook uses the terms *job* and *process* almost interchangeably
- Process – a program in execution; process execution must progress in sequential fashion
- A process includes:
  - program counter
  - stack
  - data section

# Processes in Memory

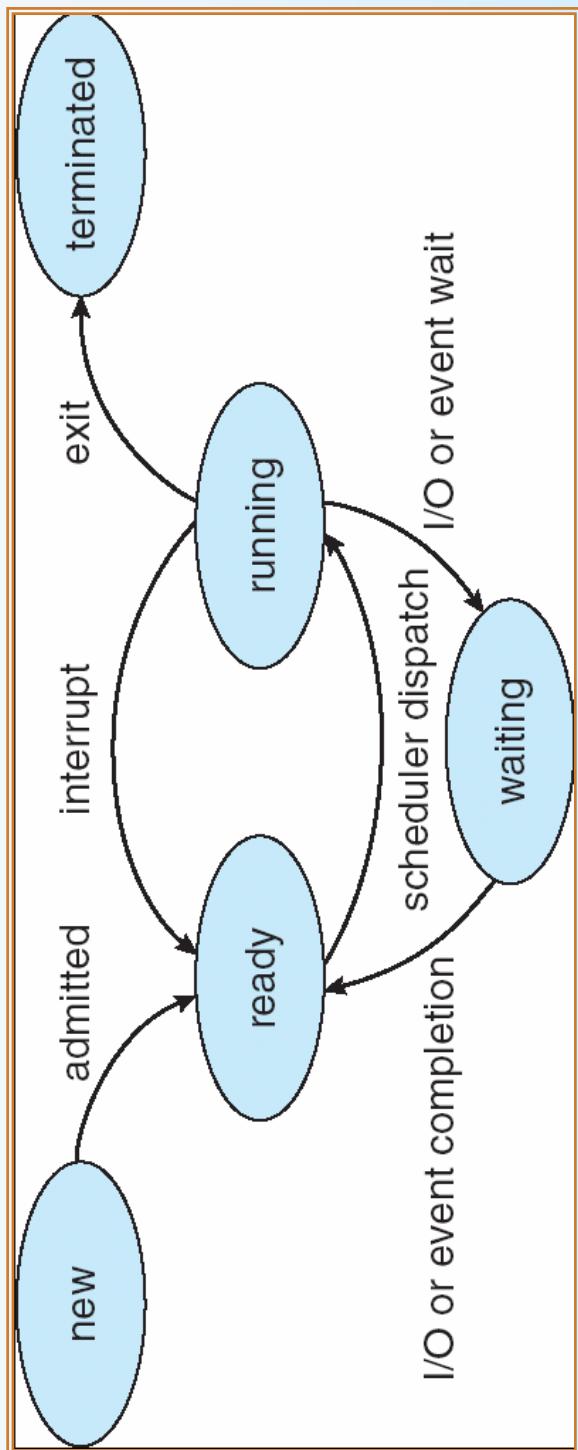

# Process State

- As a process executes, it changes state
  - **new:** The process is being created
  - **running:** Instructions are being executed
  - **waiting:** The process is waiting for some event to occur
  - **ready:** The process is waiting to be assigned to a process
  - **terminated:** The process has finished execution

# Diagram of Process State

# Process Control Block (PCB)

Information associated with each process

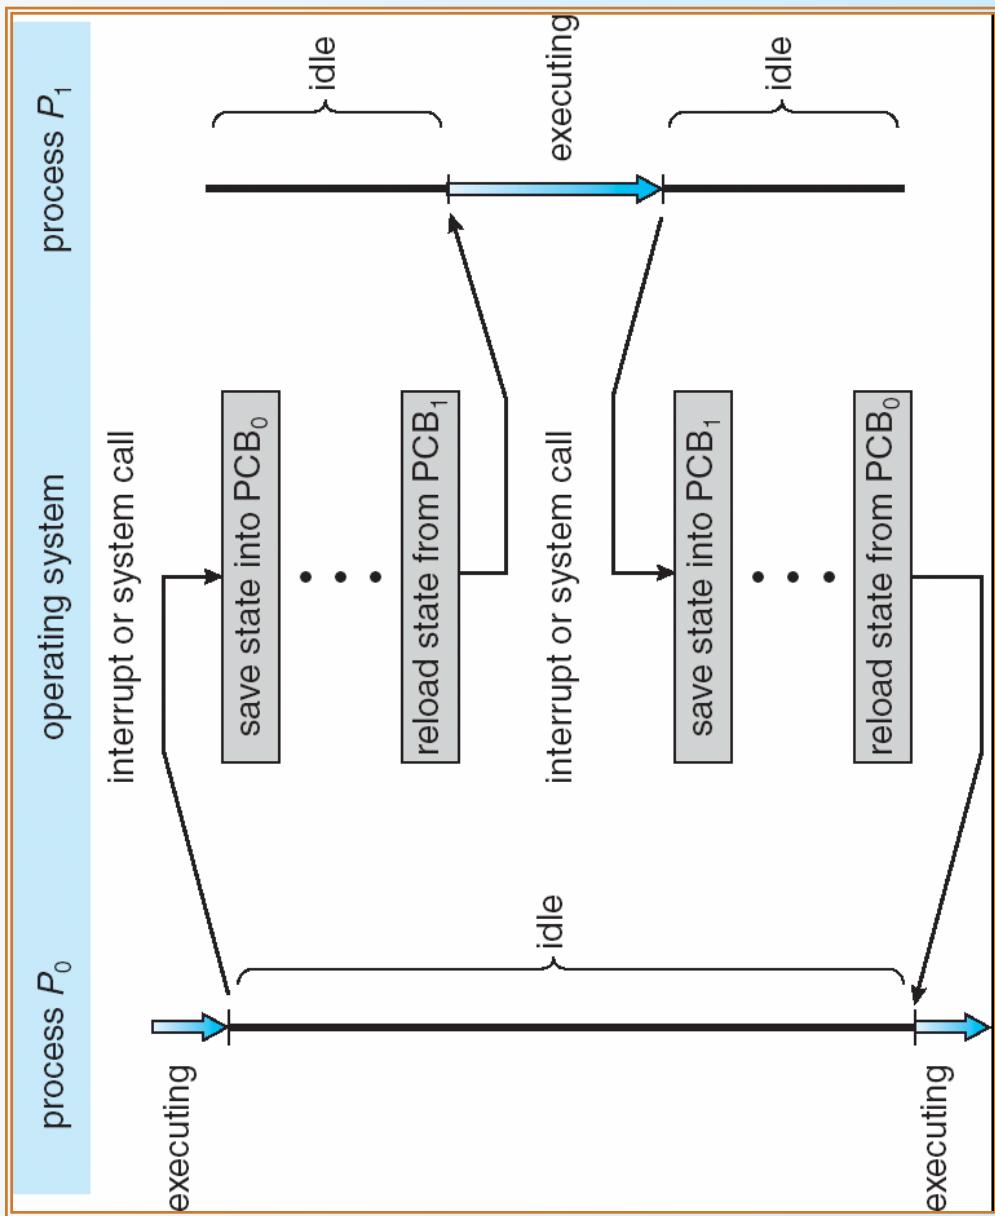

- Process state
- Program counter
- CPU registers
- CPU scheduling information
- Memory-management information
- Accounting information
- I/O status information

# Process Control Block (PCB)

# CPU Switch From Process to Process

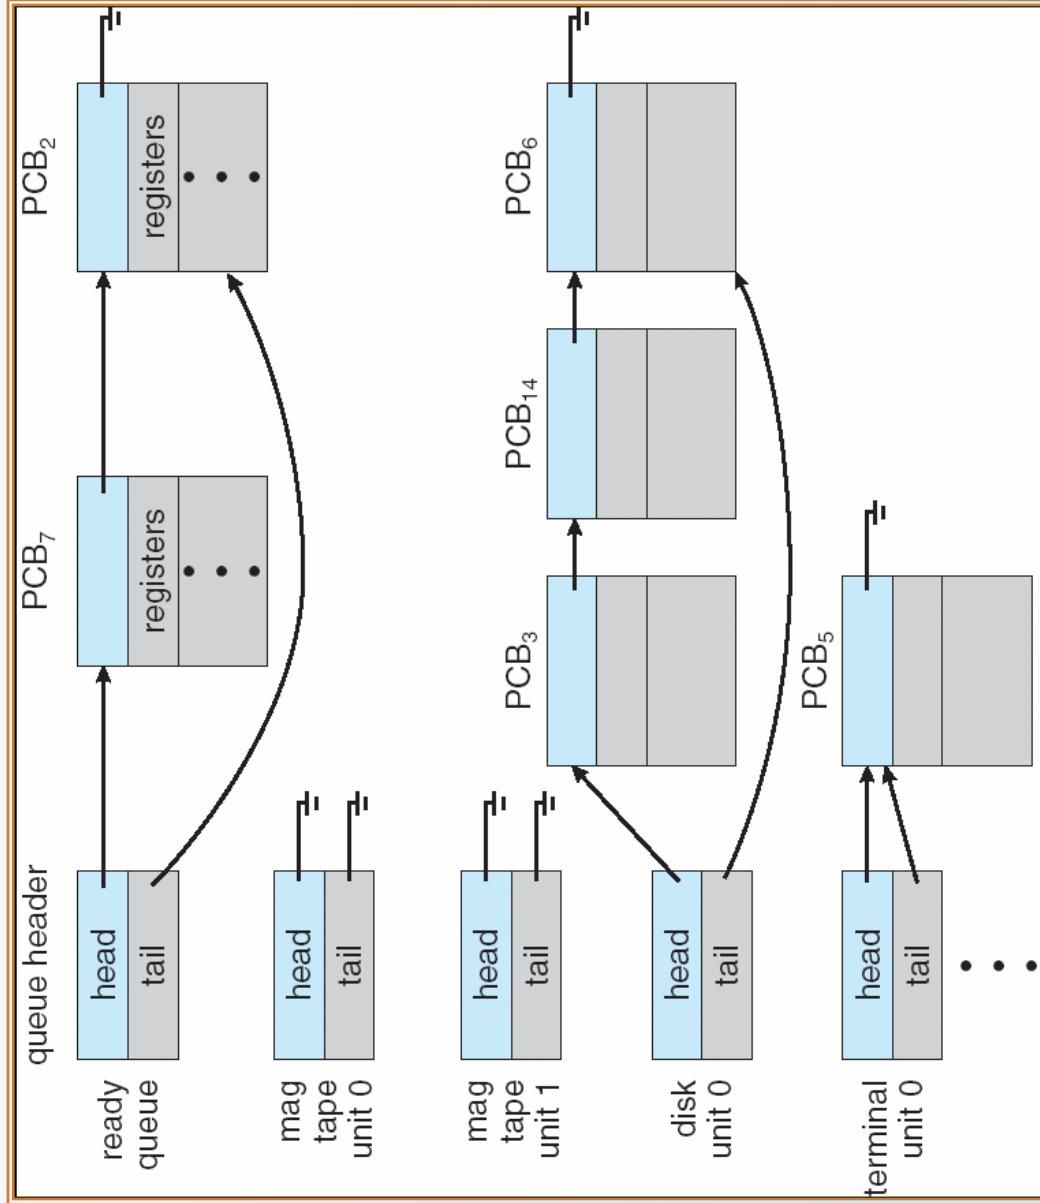

# Process Scheduling Queues

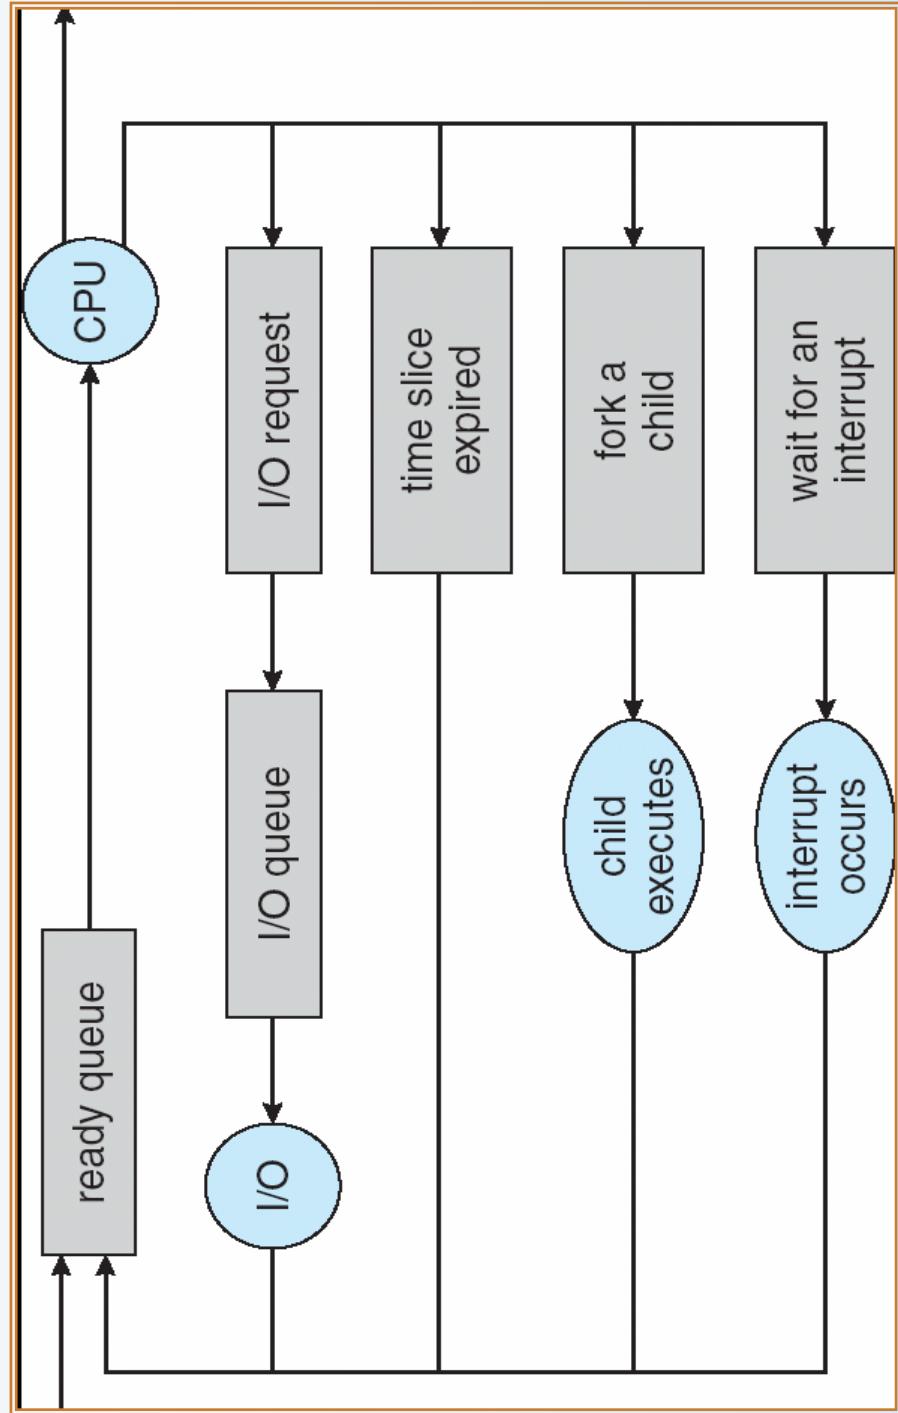

- **Job queue** – set of all processes in the system
- **Ready queue** – set of all processes residing in main memory, ready and waiting to execute
- **Device queues** – set of processes waiting for an I/O device
- Processes migrate among the various queues

# Ready Queue And Various I/O Device Queues

# Representation of Process Scheduling

# Schedulers

- **Long-term scheduler** (or job scheduler) – selects which processes should be brought into the ready queue
- **Short-term scheduler** (or CPU scheduler) – selects which process should be executed next and allocates CPU

# Schedulers (Cont.)

- Short-term scheduler is invoked very frequently (milliseconds)  $\Rightarrow$  (must be fast)
- Long-term scheduler is invoked very infrequently (seconds, minutes)  $\Rightarrow$  (may be slow)
- The long-term scheduler controls the *degree of multiprogramming*
- Processes can be described as either:
  - **I/O-bound process** – spends more time doing I/O than computations, many short CPU bursts
  - **CPU-bound process** – spends more time doing computations; few very long CPU bursts

# Context Switch

- When CPU switches to another process, the system must save the state of the old process and load the saved state for the new process
- Context-switch time is overhead; the system does no useful work while switching
- Time dependent on hardware support

# Process Creation

- Parent process create children processes, which, in turn create other processes, forming a tree of processes
- Resource sharing
  - Parent and children share all resources
  - Children share subset of parent's resources
  - Parent and child share no resources
- Execution
  - Parent and children execute concurrently
  - Parent waits until children terminate

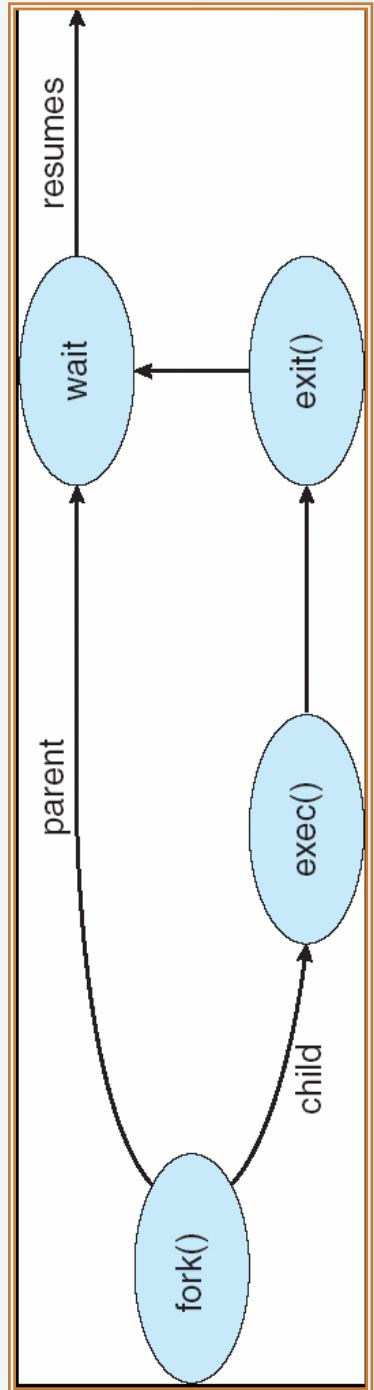

# Process Creation (Cont.)

- Address space
  - Child duplicate of parent
  - Child has a program loaded into it
- UNIX examples
  - **fork** system call creates new process
  - **exec** system call used after a **fork** to replace the process' memory space with a new program

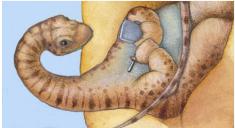

# Process Creation

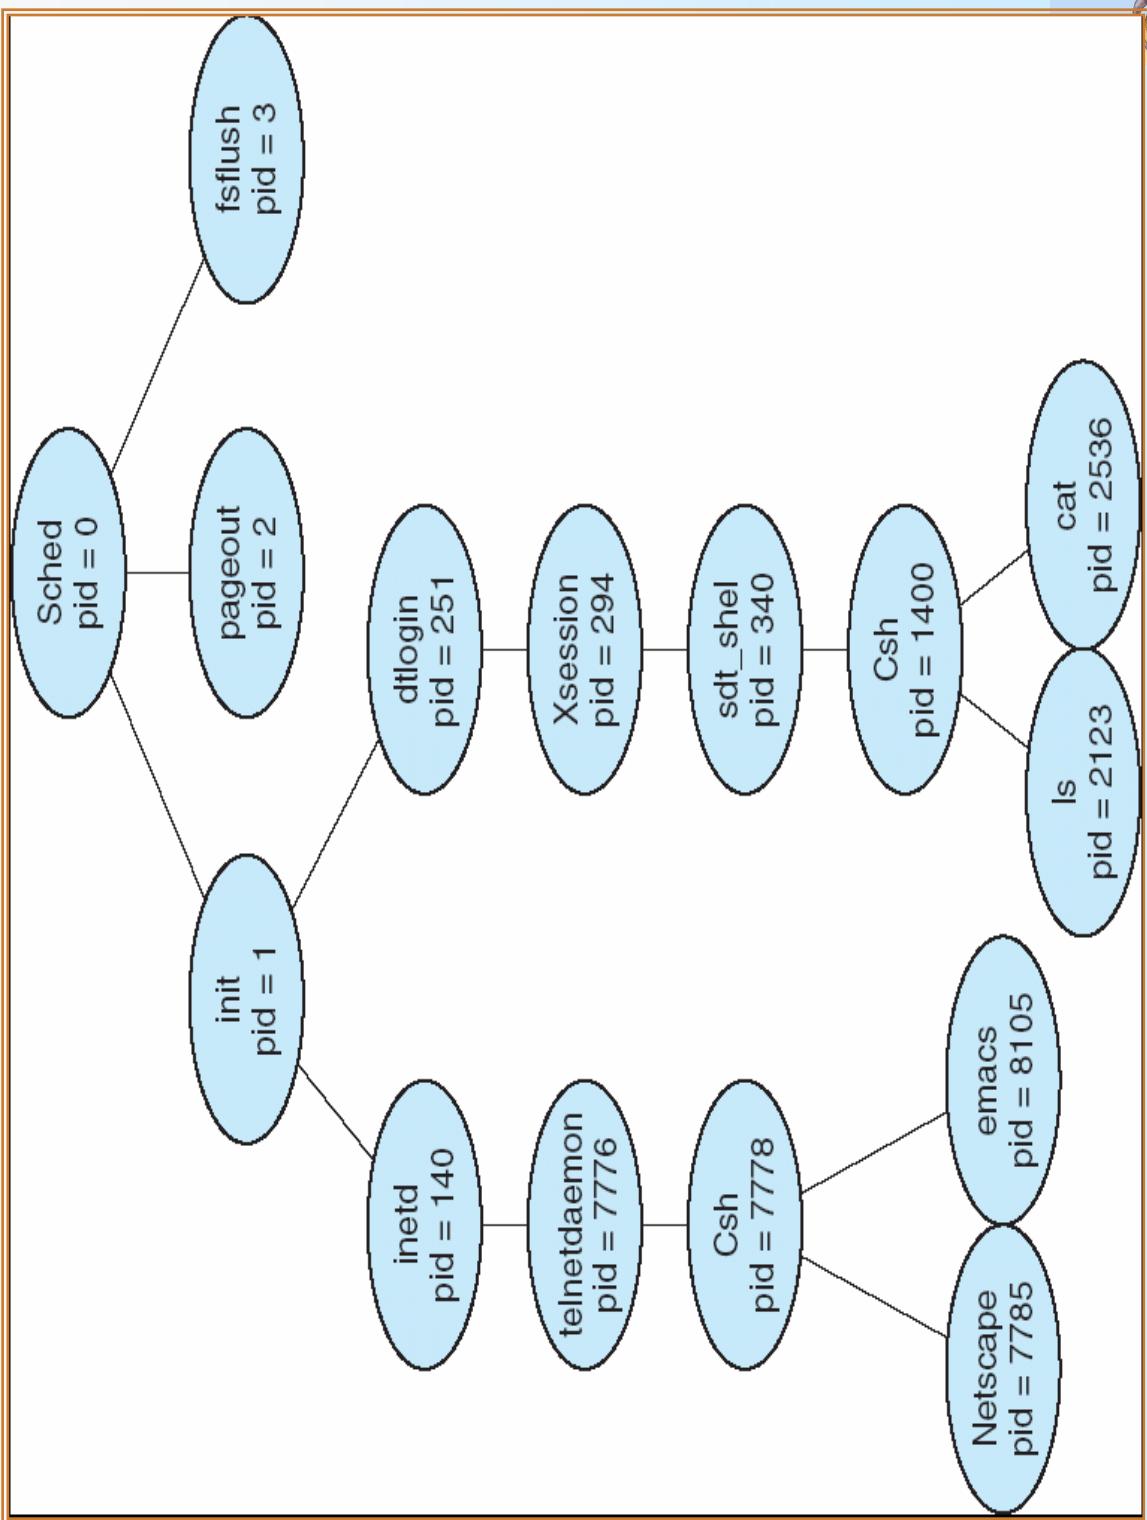

# C Program Forking Separate Process

```
int main()
```

```
{    Pid_t pid;
    /* fork another process */
    pid = fork();
    if (pid < 0) { /* error occurred */
        fprintf(stderr, "Fork Failed");
        exit(-1);
    }
    else if (pid == 0) { /* child process */
        execp("./bin/lS", "|S", NULL);
    }
    else { /* parent process */
        /* parent will wait for the child to complete */
        wait(NULL);
        printf ("Child Complete");
        exit(0);
    }
}
```

# A tree of processes on a typical Solaris

# Process Termination

- Process executes last statement and asks the operating system to delete it (**exit**)
  - Output data from child to parent (via **wait**)
  - Process' resources are deallocated by operating system
- Parent may terminate execution of children processes (**abort**)
  - Child has exceeded allocated resources
  - Task assigned to child is no longer required
  - If parent is exiting
    - ▶ Some operating system do not allow child to continue if its parent terminates
      - All children terminated - *cascading termination*

# Cooperating Processes

- **Independent** process cannot affect or be affected by the execution of another process
- **Cooperating** process can affect or be affected by the execution of another process
- Advantages of process cooperation
  - Information sharing
  - Computation speed-up
  - Modularity
  - Convenience

# Producer-Consumer Problem

- Paradigm for cooperating processes, *producer* process produces information that is consumed by a *consumer* process
  - *unbounded-buffer* places no practical limit on the size of the buffer
  - *bounded-buffer* assumes that there is a fixed buffer size

# Bounded-Buffer – Shared-Memory Solution

- Shared data

```
#define BUFFER_SIZE 10  
  
typedef struct {  
    ...  
} item;
```

```
item buffer[BUFFER_SIZE];  
  
int in = 0;  
  
int out = 0;
```

- Solution is correct, but can only use BUFFER\_SIZE-1 elements

# Bounded-Buffer – Insert( ) Method

```
/* The “producer” process */  
while ( true ) /* for(;;) */  
{  
    /* Produce an item */  
  
    /* wait for a place to put the new item */  
    while (((in + 1) % BUFFER SIZE ) == out)  
        ; /* do nothing -- no free buffers */  
  
    buffer[ in ] = item;  
    in = ( in + 1 ) % BUFFER SIZE;  
}
```

# Bounded Buffer – Remove( ) Method

```
/* the “Consumer” process */
while ( true ) /* for( ; ; ) */
{
    while (in == out)
        ; /* do nothing -- nothing to consume */

    /* remove an item from the buffer */
    item = buffer[ out ];
    out = (out + 1) % BUFFER_SIZE;

    /* do something with item */
}
```

# Interprocess Communication (IPC)

- Mechanism for processes to communicate and to synchronize their actions
- Message system – processes communicate with each other without resorting to shared variables
- IPC facility provides two operations:
  - **send(message)** – message size fixed or variable
  - **receive(message)**
- If  $P$  and  $Q$  wish to communicate, they need to:
  - establish a *communication link* between them
  - exchange messages via send/receive
- Implementation of communication link
  - physical (e.g., shared memory, hardware bus)
  - logical (e.g., logical properties)

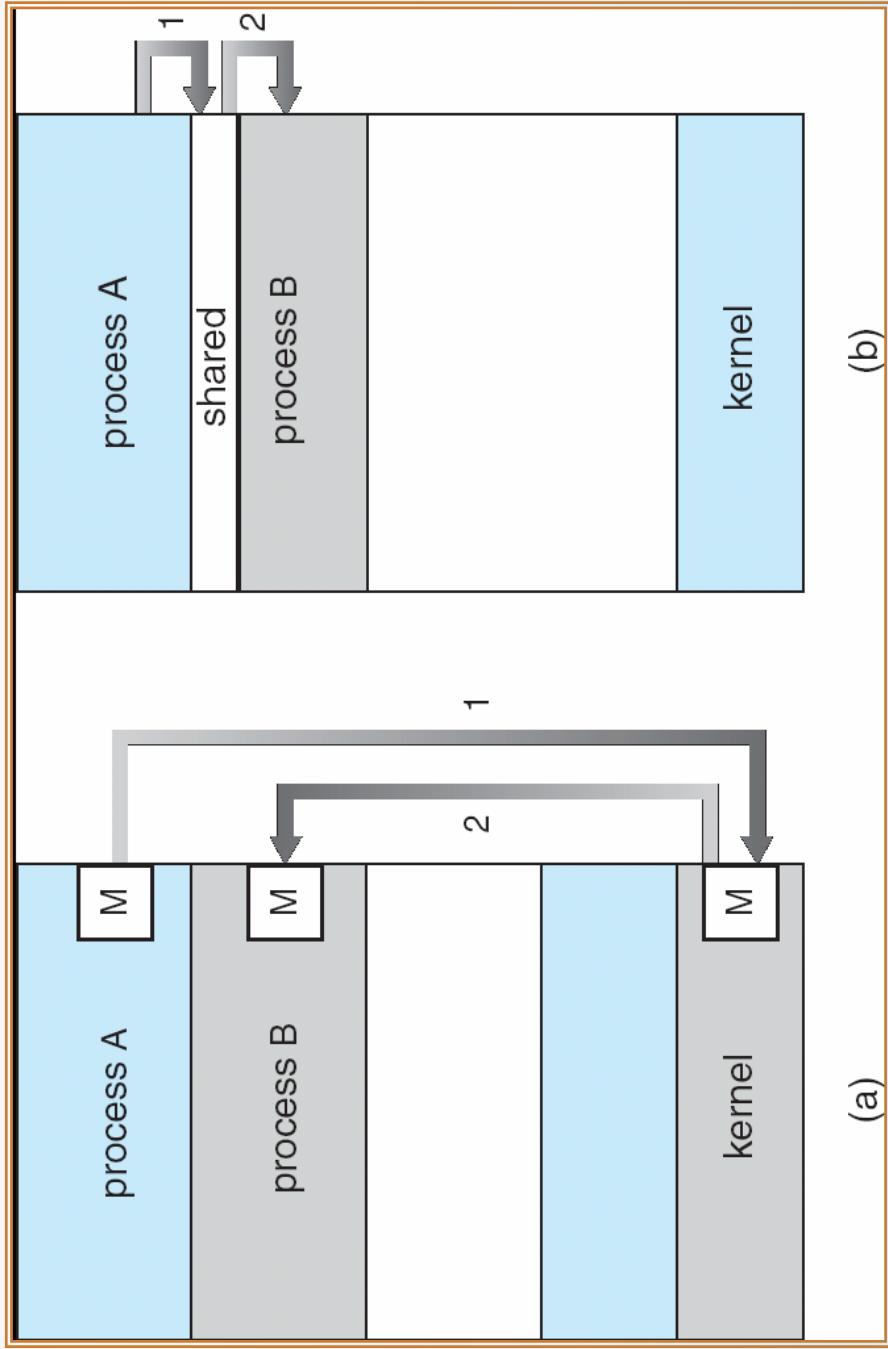

# Implementation Questions

- How are links established?
- Can a link be associated with more than two processes?
- How many links can there be between every pair of communicating processes?
- What is the capacity of a link?
- Is the size of a message that the link can accommodate fixed or variable?
- Is a link unidirectional or bi-directional?

# Communications Models

# Direct Communication

- Processes must name each other explicitly:
  - **send** ( $P$ , message) – send a message to process  $P$
  - **receive**( $Q$ , message) – receive a message from process  $Q$
- Properties of communication link
  - Links are established automatically
  - A link is associated with exactly one pair of communicating processes
  - Between each pair there exists exactly one link
  - The link may be unidirectional, but is usually bi-directional

# Indirect Communication

- Messages are directed and received from mailboxes (also referred to as ports)
  - Each mailbox has a unique id
  - Processes can communicate only if they share a mailbox
- Properties of communication link
  - Link established only if processes share a common mailbox
  - A link may be associated with many processes
  - Each pair of processes may share several communication links
  - Link may be unidirectional or bi-directional

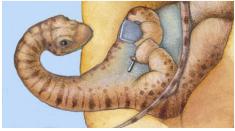

# Indirect Communication

- Operations
  - create a new mailbox
  - send and receive messages through mailbox
  - destroy a mailbox
- Primitives are defined as:
  - $\text{send}(A, \text{message})$  – send a message to mailbox A
  - $\text{receive}(A, \text{message})$  – receive a message from mailbox A

# Indirect Communication

- Mailbox sharing
  - $P_1$ ,  $P_2$ , and  $P_3$  share mailbox A
  - $P_1$ , sends;  $P_2$  and  $P_3$  receive
  - Who gets the message?
- Solutions
  - Allow a link to be associated with at most two processes
  - Allow only one process at a time to execute a receive operation
  - Allow the system to select arbitrarily the receiver. Sender is notified who the receiver was.

# Synchronization

- Message passing may be either blocking or non-blocking
- **Blocking** is considered **synchronous**
  - **Blocking send** has the sender block until the message is received
  - **Blocking receive** has the receiver block until a message is available
- **Non-blocking** is considered **asynchronous**
  - **Non-blocking** send has the sender send the message and continue
  - **Non-blocking** receive has the receiver receive a valid message or null

# Buffering

- Queue of messages attached to the link; implemented in one of three ways
  1. Zero capacity – 0 messages  
Sender must wait for receiver (rendezvous)
  2. Bounded capacity – finite length of  $n$  messages  
Sender must wait if link full
  3. Unbounded capacity – infinite length  
Sender never waits

# Client-Server Communication

- Sockets
- Remote Procedure Calls
- Remote Method Invocation (Java)

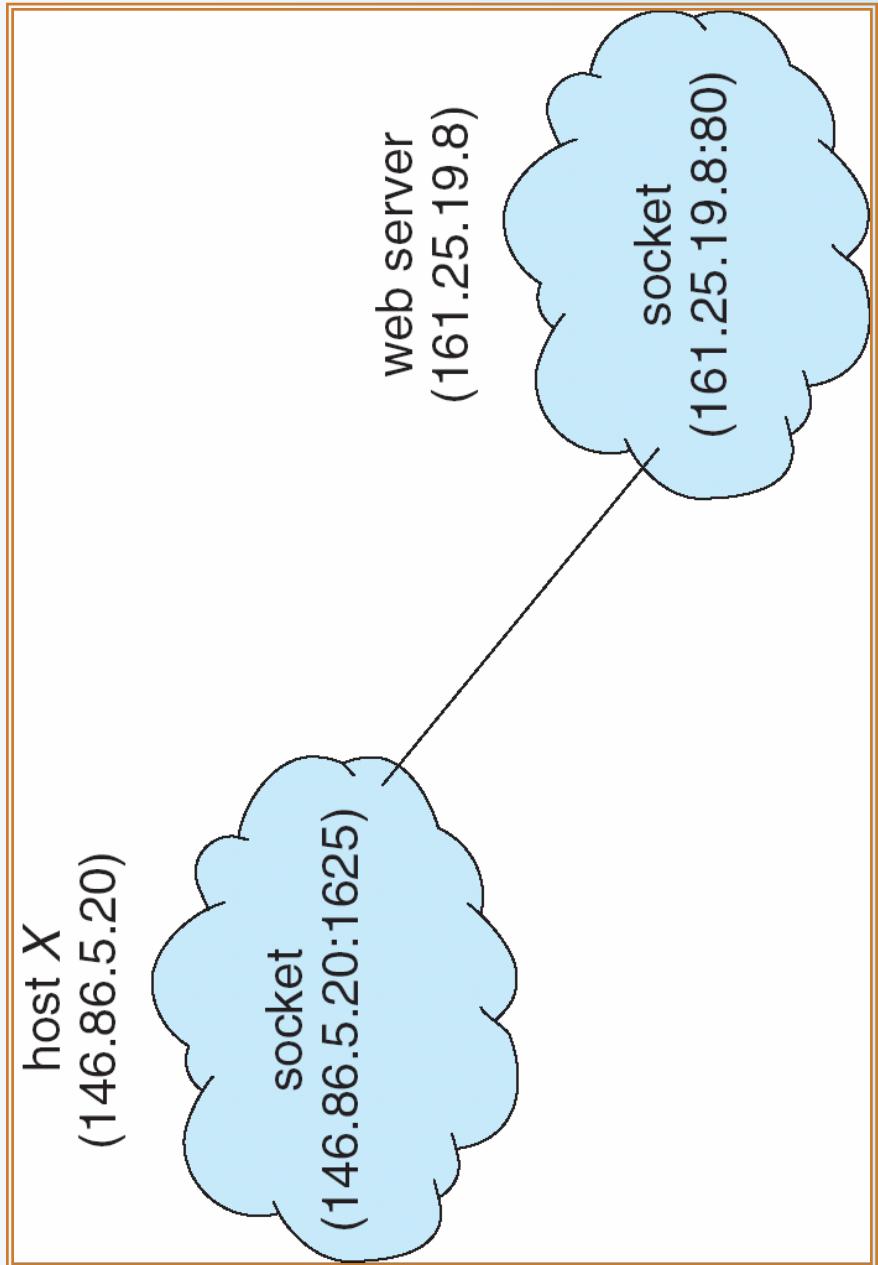

# Sockets

- A socket is defined as an *endpoint for communication*
- Concatenation of IP address and port
- The socket **161.25.19.8:1625** refers to port **1625** on host **161.25.19.8**
- Communication consists between a pair of sockets

# Socket Communication

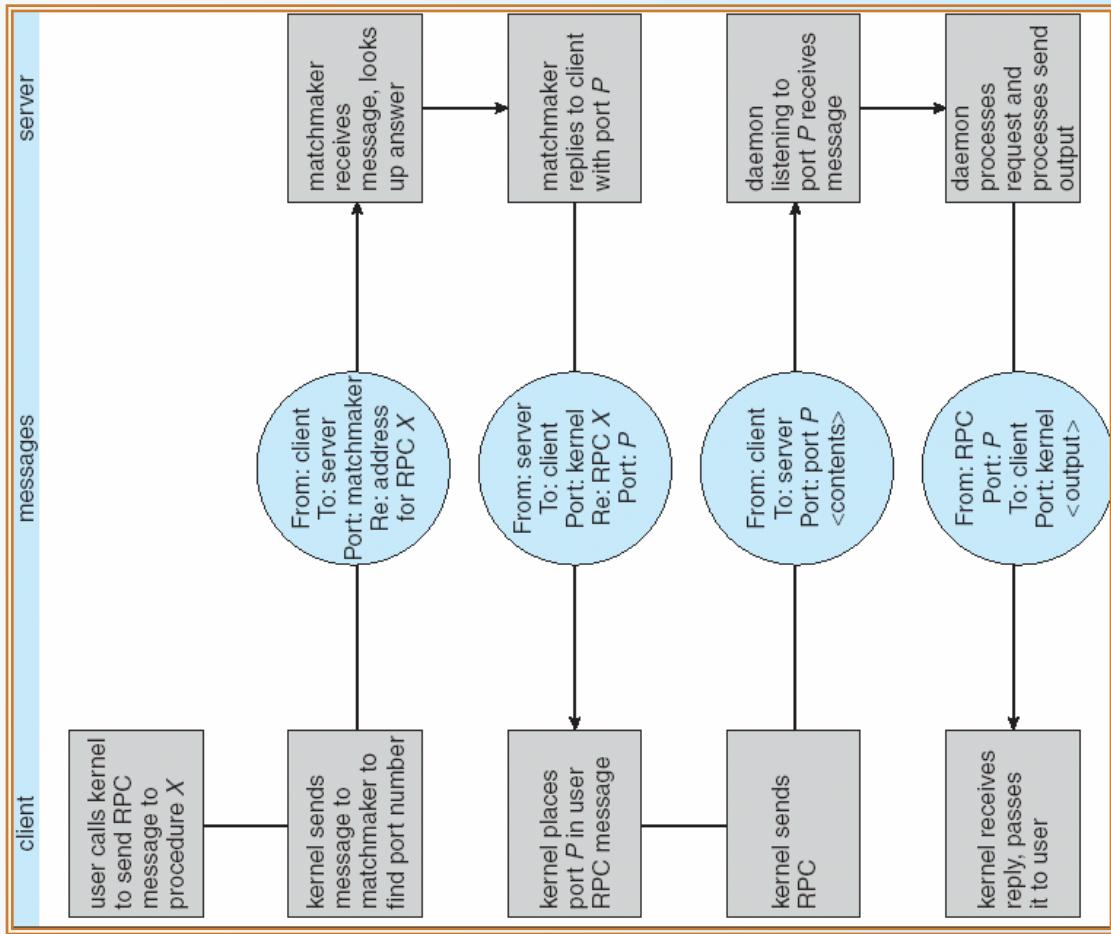

# Remote Procedure Calls

- Remote procedure call (RPC) abstracts procedure calls between processes on networked systems.
- **Stubs** – client-side proxy for the actual procedure on the server.
  - The client-side stub locates the server and *marshalls* the parameters.
  - The server-side stub receives this message, unpacks the marshalled parameters, and performs the procedure on the server.

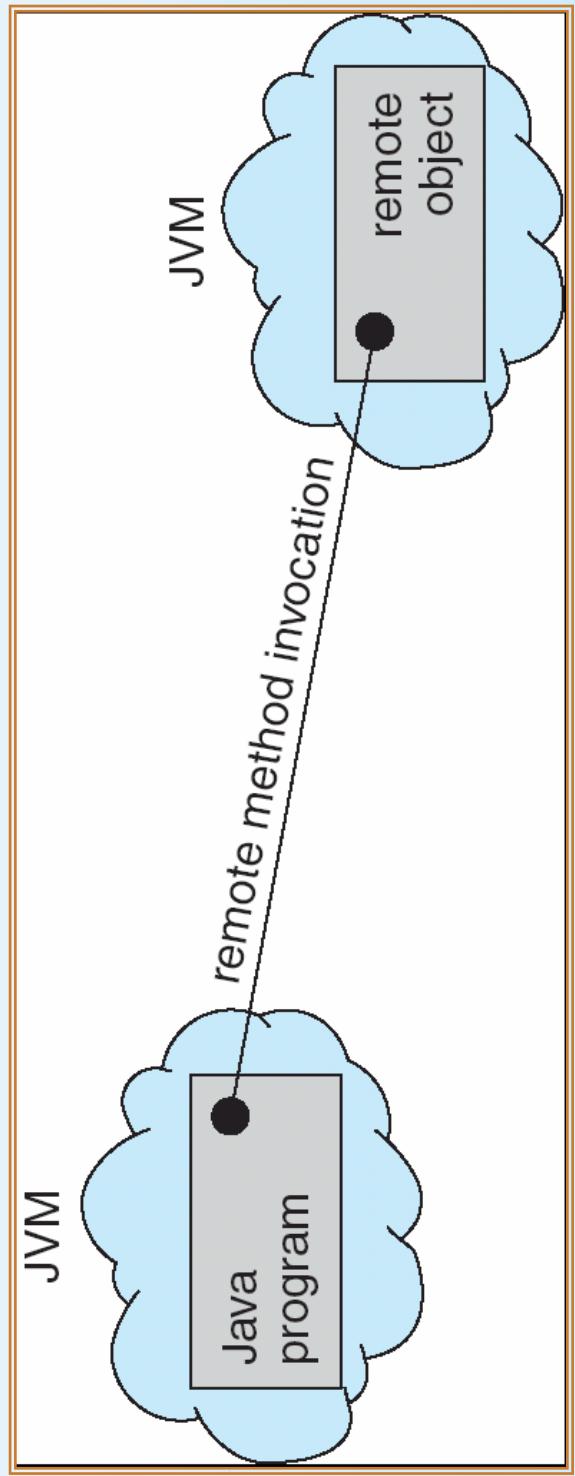

# Execution of RPC

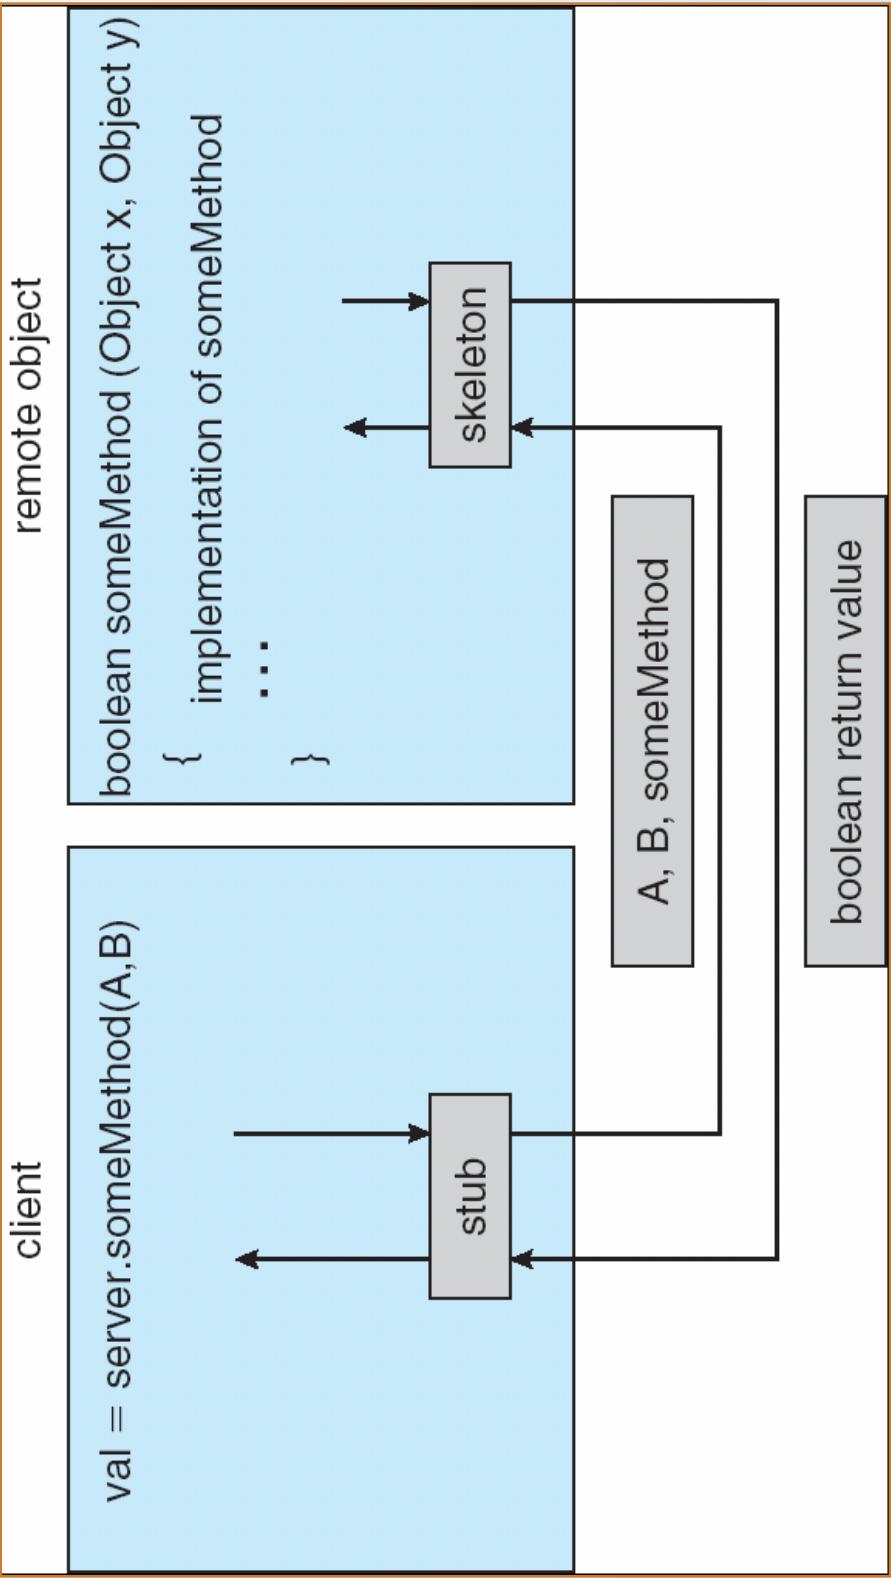

# Remote Method Invocation

- Remote Method Invocation (RMI) is a Java mechanism similar to RPCs.
- RMI allows a Java program on one machine to invoke a method on a remote object.

# Marshalling Parameters

# **End of Chapter 3**
