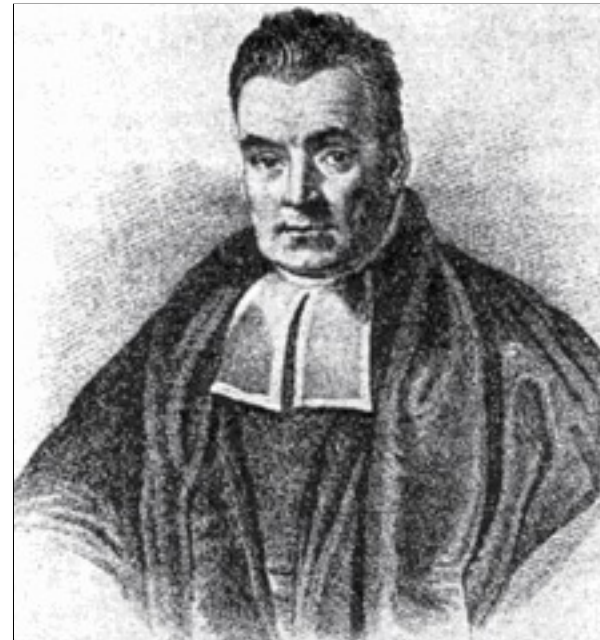
Bayesian Reasoning

Chapters 12 & 13



Thomas Bayes, 1701-1761

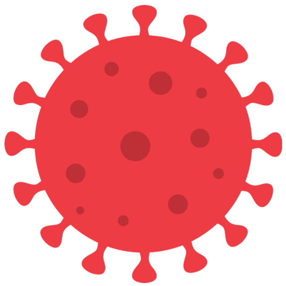
Today's topics

- Motivation
- Review probability theory
- Bayesian inference
  - From the joint distribution
  - Using independence/factoring
  - From sources of evidence
- Naïve Bayes algorithm for inference and classification tasks

Motivation: causal reasoning

- As the sun rises, the rooster crows
  - Does this correlation imply causality?
  - If so, which way does it go?
- The evidence can come from
  - Probabilities and Bayesian reasoning
  - Common sense knowledge
  - Experiments
- Bayesian Belief Networks (BBNs) are useful for modeling causal reasoning

Motivation: logic isn't enough



- Classical logic is designed to work with certainties
- Getting a positive result on a COVID test doesn't necessarily mean you are infected
- And a negative result doesn't necessarily mean you are not infected
- You need to know the **true/false positive** and **true/false negative** rates of the test

Decision making with uncertainty 🤔

Rational behavior: for each possible action:

- Identify possible outcomes and **for each**
  - Compute **probability** of outcome
  - Compute **utility** of outcome
  - Compute probability-weighted **(expected) utility** of outcome
- Select action with the highest expected utility (principle of **Maximum Expected Utility**)

Consider

- Your house has an alarm system
- It should go off if a burglar breaks into the house
- It can also go off if there is an earthquake
- How can we predict what’s happened if the alarm goes off?
  - Someone has broken in!
  - It’s a minor earthquake

Probability theory 101

- **Random variables:**
  - Domain
- **Atomic event**: complete specification of state
- **Prior probability**: degree of belief without any other evidence or info
- **Joint probability**: matrix of combined probabilities of set of variables

- Alarm, Burglary, Earthquake

Boolean (these) or discrete (0-9), continuous (float)

- Alarm=T∧Burglary=T∧Earthquake=F
  alarm ∧ burglary ∧ ¬earthquake

- P(Burglary) = 0.1
  P(Alarm) = 0.1
  P(earthquake) = 0.000003

- P(Alarm, Burglary) =

	alarm	**¬alarm**
burglary	.09	.01
¬burglary	.1	.8

Probability theory 101

	alarm	¬alarm
burglary	.09	.01
¬burglary	.1	.8

- **Conditional probability**: prob. of effect given causes
- **Computing conditional probs**:
  - $P(a \mid b) = P(a \wedge b) / P(b)$
  - $P(b)$: **normalizing** constant
- **Product rule**:
  - $P(a \wedge b) = P(a \mid b) * P(b)$
- **Marginalizing**:
  - $P(B) = \Sigma_a P(B, a)$
  - $P(B) = \Sigma_a P(B \mid a)\, P(a)$ (**conditioning**)

- $P(\text{burglary} \mid \text{alarm}) = .47$
  $P(\text{alarm} \mid \text{burglary}) = .9$
- $P(\text{burglary} \mid \text{alarm}) =$
  $P(\text{burglary} \wedge \text{alarm}) / P(\text{alarm})$
  $= .09/.19 = .47$
- $P(\text{burglary} \wedge \text{alarm}) =$
  $P(\text{burglary} \mid \text{alarm}) * P(\text{alarm})$
  $= .47 * .19 = .09$
- $P(\text{alarm}) =$
  $P(\text{alarm} \wedge \text{burglary}) +$
  $P(\text{alarm} \wedge \neg\text{burglary})$
  $= .09+.1 = .19$

Probability theory 101

	alarm	¬alarm
burglary	.09	.01
¬burglary	.1	.8

- **Conditional probability**: prob. of effect given causes
- **Computing conditional probs**:
  - $P(a \mid b) = P(a \wedge b) / P(b)$
  - $P(b)$: **normalizing** constant
- **Product rule**:
  - $P(a \wedge b) = P(a \mid b) * P(b)$
- **Marginalizing**:
  - $P(B) = \Sigma_a P(B, a)$
  - $P(B) = \Sigma_a P(B \mid a) P(a)$ (**conditioning**)

- P(burglary | alarm) = .47
  P(alarm | burglary) = .9
- P(burglary | alarm) =
  P(burglary ∧ alarm) / P(alarm)
  = .09/.19 = .47
- P(burglary ∧ alarm) =
  P(burglary | alarm) * P(alarm)
  = .47 * .19 = .09
- P(alarm) =
  P(alarm ∧ burglary) +
  P(alarm ∧ ¬burglary)
  = .09+.1 = .19

Example: Inference from the joint

	alarm		¬alarm	
	earthquake	**¬earthquake**	**earthquake**	**¬earthquake**
burglary	.01	.08	.001	.009
¬burglary	.01	.09	.01	.79

P(burglary | alarm) = α P(burglary, alarm)

= α [P(burglary, alarm, earthquake) + P(burglary, alarm, ¬earthquake)

= α [(.01, .01) + (.08, .09)]

= α [(.09, .1)]

Since P(burglary | alarm) + P(¬burglary | alarm) = 1, α = 1/(.09+.1) = 5.26

(i.e., P(alarm) = 1/α = .19 – **quizlet**: how can you verify this?)

P(burglary | alarm) = .09 * 5.26 = .474

P(¬burglary | alarm) = .1 * 5.26 = .526

Consider

- A student has to take an exam
  - She might **be smart**
  - She might **have studied**
  - She may **be prepared** for the exam
- How are these related?
- We can collect joint probabilities for the three events
  - Measure “prepared” as “got a passing grade”

Exercise: Inference from the joint

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Each of the 8 highlighted boxes has the joint probability for the three values of smart, study, prepared

Standard way to show joint probabilities of 3 variables as a 2D table

Queries:

- **What is the prior probability of *smart*?**
- What is the prior probability of *study*?
- What is the conditional probability of *prepared*, given *study* and *smart*?

Exercise:
Inference from the joint

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Queries:

- **What is the prior probability of *smart*?**
- What is the prior probability of *study*?
- What is the conditional probability of *prepared*, given *study* and *smart*?

p(smart) = .432 + .16 + .048 + .16 = **0.8**

Exercise:
Inference from the joint

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Queries:

- What is the prior probability of *smart*?
- **What is the prior probability of *study*?**
- What is the conditional probability of *prepared*, given *study* and *smart*?

Exercise:
Inference from the joint

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Queries:

- What is the prior probability of *smart*?
- **What is the prior probability of *study*?**
- What is the conditional probability of *prepared*, given *study* and *smart*?

p(study) = .432 + .048 + .084 + .036 = **0.6**

Exercise:
Inference from the joint

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Queries:

- What is the prior probability of *smart*?
- What is the prior probability of *study*?
- **What is the conditional probability of *prepared*, given *study* and *smart*?**

Exercise:
Inference from the joint

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Queries:

– What is the prior probability of *smart*?

– What is the prior probability of *study*?

– **What is the conditional probability of *prepared*, given *study* and *smart*?**

p(prepared|smart,study)= p(prepared,smart,study)/p(smart, study)
= .432 / (.432 + .048)
= **0.9**

Independence

- When variables don't affect each others' probabilities, they are **independent;** we can easily compute their joint & conditional probability:

  Independent(A, B) → $P(A \wedge B) = P(A) * P(B)$; $P(A|B) = P(A)$

- {moonPhase, lightLevel} *might* be independent of {burglary, alarm, earthquake}
  - Maybe not: burglars may be more active during a new moon because darkness hides their activity
  - But if we know light level, moon phase doesn't affect whether we are burglarized
  - If burglarized, light level doesn't affect if alarm goes off
- Need a more complex notion of independence and methods for **reasoning about the relationships**

Exercise: Independence

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Queries:

- **Q1: Is *smart* independent of *study*?**
- **Q2: Is *prepared* independent of *study*?**

How can we tell?

Exercise: Independence

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Q1: Is *smart* independent of *study*?

- You might have some **intuitive beliefs** based on your experience
- You can also **check the data**

Which way to answer this is better?

Exercise: Independence

p(smart ∧ study ∧ prepared)	smart		¬smart	
	study	¬study	study	¬study
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Q1: Is *smart* independent of *study*?

Q1 true iff p(smart|study) == p(smart)

p(smart) = .432 + 0.048 + .16 + .16 = **0.8**

p(smart|study) = p(smart,study)/p(study)

= (.432 + .048) / .6 = 0.48/.6 = **0.8**

0.8 == 0.8 ∴ **smart is independent of study**

Exercise: Independence

p(smart ∧ study ∧ prep)	smart		¬smart	
	study	**¬study**	**study**	**¬study**
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Q2: Is *prepared* independent of *study*?

- What is prepared?
- Q2 true iff

Exercise: Independence

p(smart ∧ study ∧ prep)	smart		¬smart	
	study	**¬study**	**study**	**¬study**
prepared	.432	.16	.084	.008
¬prepared	.048	.16	.036	.072

Q2: Is *prepared* independent of *study*?

Q2 true iff p(prepared|study) == p(prepared)

p(prepared) = .432 + .16 + .84 + .008 = .684

p(prepared|study) = p(prepared,study)/p(study)

= (.432 + .084) / .6 = .86

0.86 ≠ 0.684, ∴ **prepared not independent of study**

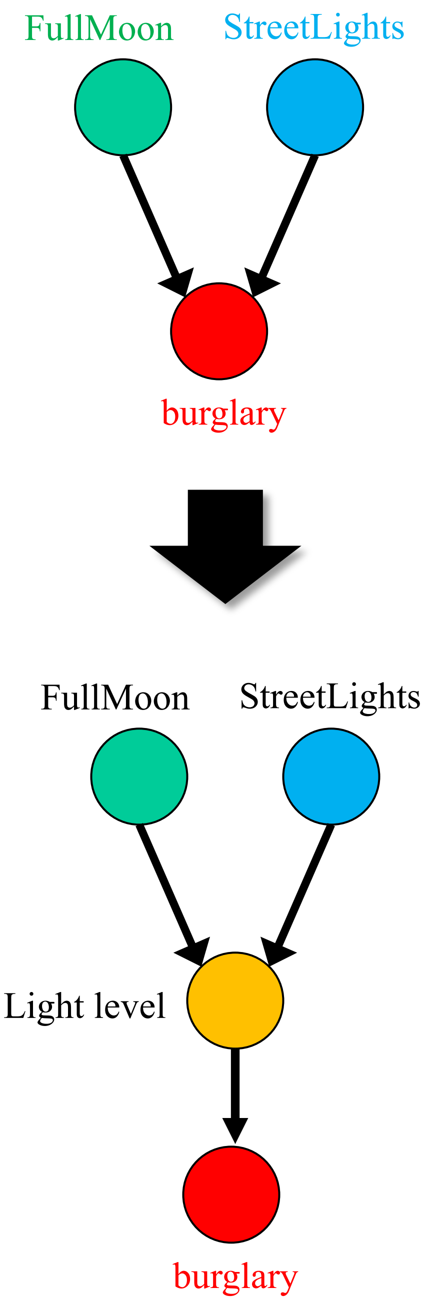
Absolute & conditional independence

- Absolute independence:
  - A and B are **independent** if $P(A \wedge B) = P(A) * P(B)$; equivalently, $P(A) = P(A \mid B)$ and $P(B) = P(B \mid A)$
- A and B are **conditionally independent** given C if
  - $P(A \wedge B \mid C) = P(A \mid C) * P(B \mid C)$

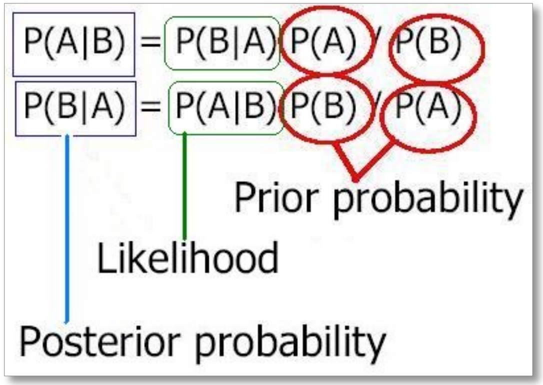
  If it holds, lets us decompose the joint distribution:
  - $P(A \wedge B \wedge C) = P(A \mid C) * P(B \mid C) * P(C)$
- Moon-Phase and Burglary are ***conditionally independent given*** Light-Level
- Conditional independence is weaker than absolute independence, but useful in decomposing full joint probability distribution

Conditional independence

- Conditional independence often comes from **causal relations**
  - FullMoon causally affects LightLevel at night as does StreetLights
- In burglary scenario, FullMoon doesn't affect anything else
- Knowing *LightLevel*, we can ignore *FullMoon* and *StreetLights* *when* predicting if alarm suggests Burglary



Bayes' rule



Derived from the product rule:

– P(A, B) = P(A|B) * P(B) *# from definition of conditional probability*

– P(B, A) = P(B|A) * P(A) *# from definition of conditional probability*

– P(A, B) = P(B, A) *# since order is not important*

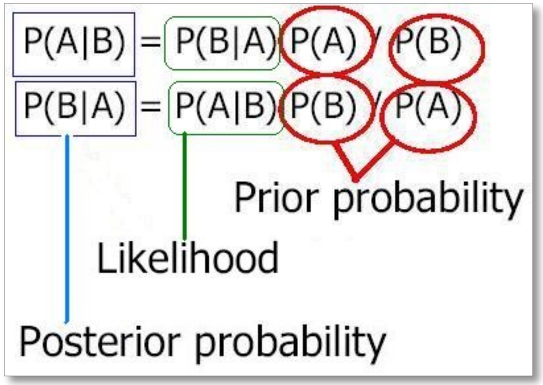
So…

$$\mathbf{P(A|B) = \frac{P(B|A) * P(A)}{P(B)}}$$

relates P(A|B) and P(B|A)

P(A,B) is probability of both A and B being true, so P(A,B) = P(B,A)

Useful for diagnosis!



- *C is a cause, E is an effect*:
  - P(C|E) = P(E|C) * P(C) / P(E)
- **Useful for diagnosis**:
  - E are (observed) effects and C are (hidden) causes,
  - Often have model for how causes lead to effects P(E|C)
  - We may have info (based on experience) on frequency of causes (P(C))
  - Which allows us to reason abductively from effects to causes (P(C|E))
  - Recall, abductive reasoning: from A => B and B, infer (maybe?) A

Example: meningitis and stiff neck

cause

symptom

- **Meningitis** (M) can cause **stiff neck** (S), though there are other causes too
- Use S as a *diagnostic symptom* & estimate $\mathbf{p(M|S)}$
- Studies can estimate $p(M)$, $p(S)$ & $p(S|M)$, e.g. $p(S|M)=0.7$, $p(S)=0.01$, $p(M)=0.00002$
- Harder to directly gather data on $p(M|S)$
- Applying Bayes' Rule:
  $p(M|S) = p(S|M) * p(M) / p(S) = 0.0014$

Summary

- Probability a rigorous formalism for uncertain knowledge
- Joint probability distribution specifies probability of every atomic event
- Answer queries by summing over atomic events
- Must reduce joint size for non-trivial domains
- Bayes rule: compute from known conditional probabilities, usually in causal direction
- Independence & conditional independence provide tools
- Next: Bayesian belief networks
