Array Declarations Revisited

int numbers[5];

- □ This declaration sets aside a chunk of memory that is big enough to hold 5 integers.
- Besides the space needed for the array, there is also a variable allocated that has the name of the array. This variable holds the address of the beginning (address of the first element) of the array.

numbers

Array Name Holds an Address

```
#include <stdio.h>
int main()
{
    int numbers[5] = {97, 68, 55, 73, 84};
    printf ("numbers[0] = %d\n", numbers[0]);
    printf ("numbers = %X\n", numbers);
    printf ("&numbers[0] = %X\n", &numbers[0]);
    return 0;
}

output

numbers[0] = 97
    numbers = FE00
    &numbers[0] = FE00
    &numbers[0] = FE00
```

Indexing Arrays

As long as we know

FE00

- the beginning location of an array,
- the data type being held in the array, and
- the size of the array (so that we don't go out of range),

then we can access or modify any of its elements using indexing.

■ The array name alone (without []) is just a variable that contains the starting address of the block of memory where the array is held.

Call (Pass) by Value

- □ So far, we have passed only values to functions.
- □ The function has a local variable (a formal parameter) to hold its own copy of the value passed in.
- When we make changes to this copy, the original (the corresponding actual parameter) remains unchanged.
- □ This is known as calling (passing) by value.

Passing Arrays to Functions

- The function prototype:
 - void fillArray (int ages[], int numElements);
- The function definition header: void fillArray (int ages[], int numElements)
- The function call:
 - fillArray (ages, SIZE);
- Notice that we are passing only the name of the array (the address) and that we aren't returning anything (the function is void) because we will be modifying the original array from within the function.

Call (Pass) by Reference

- □ As demonstrated with arrays, we can pass addresses to functions. This is known as calling (passing) by reference.
- □ When the function is passed an address, it can make changes to the original (the corresponding actual parameter). There is no copy made.
- ☐ This is great for arrays, because arrays are usually very large. We really don't want to make a copy of an array. It would use too much memory.

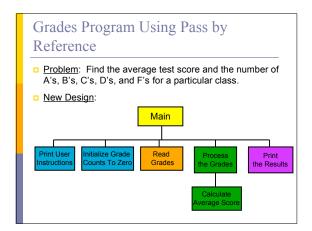

Passing an Array to a Function

```
#include <stdio.h>
#define SIZE 4
void fillArray (int intArray[], int size);
int main ()
   int someArray [SIZE];
   fillArray (someArray, SIZE);
/* Print the elements of the array */
for ( i = 0; i < SIZE; i++ )
      return 0 ;
                      someArray[0] = 0
                     someArray[1] = 1
someArray[2] = 2
         output
```

someArray[3] = 3

fillArray is a function that will fill each element of any integer array passed to it with a value that is the same as that element's subscript.

void fillArray (int anArray[], int numElements) for (i = 0; i < numElements; i++) anArray [i] = i ; }

```
#include <stdio.h>
#define SIZE 39
#define GRADES 5
#define A 4
#define B 3
#define D 1
#define D 1
#define MAX 100
#define MIN 0
void printInstructions ();
void initArray (int anArray[], int size);
void fillArray (int anArray[], int size);
double findAverage (double sum, int num);
void printResults (double average, int gradeCount[]);
```

"Clean" Grades Program (cont.)

```
/* initArray - initializes an integer array to all zeros
/* inputs: anArray - array to be initialized
/* size - size of the array
/* Outputs: None
/* void initArray (int anArray [], int size)
{
    for ( i = 0; i < size; i++ )
    {
        anArray [ i ] = 0;
    }
}
```

```
"fillArray - fills an integer array with valid values that are entered by the user.

Assures the values are between MIN and MAX.

Inputs: anArray - array to fill

Outputs: size - size of the array

ioide Effect - MiN and MAX must be #defined in this file

void fillArray (int anArray [], int size)

(inti; /* loop counter */
for (i = 0; i < size; i++) //
printf ("Enter next value"; );
scan ("Enter next value"; );
scan ("Enter next value"; );
scan ("Enter next value"; );
printf ("Enter next value"; );
scan ("Max"ay [] | MAX) ) {
printf ("Enter next value"; );
scan ("Max"ay [] | MAX) }
}
```

"Clean" Grades Program (cont.)

```
/**findAverage - calculates an average
*** Inputs: sum - the sum of all values
*** num - the number of values
*** Outputs: the computed average

double findAverage (double sum, int num)
{
    double average ; /* computed average */
    if (num!=0) {
        average = sum / num;
    }
    else {
        average = 0;
}

return average ;
}
```

```
*** printResults - prints the class average and the grade distribution for the class.

*** Inputs: average - class average

*** gradeCount - number of A's, B's, C's, D's, and F's

*** Outputs: None

** Side Effect: A, B, C, D, and F must be #defined in this file

/**

void printResults (double average, int gradeCount []) {

printf ("The class average is %.2\n", average );

printf ("There were %2d As\n", gradeCount [A]);

printf (" %2d As\n", gradeCount [B]);

printf (" %2d Ds\n", gradeCount [C]);

printf (" %2d Ds\n", gradeCount [F]);

}
```
